

POWERBI EXAM

1. Power BI is a Business Intelligence (BI) and Data Visualization tool developed by Microsoft. It connects to different data sources, cleans data, and creates reports and dashboards.

2.

Sales Analysis

Financial reporting

3.

Merge Query

Combines tables horizontally (adds columns).

Uses a common column (key).

Similar to SQL JOIN.

Append Query

Combines tables vertically (adds rows).

Does not require a common key.

Similar to SQL UNION.

4.

First Load the table in PBI,

Take model view in PBI

Find common column in tables

Drag common column from one table in
to other table

5.

Calculated Column

Calculated row by row during data refresh.

Stored in the model.

Increases model size.

Measure

Calculated dynamically when used in a visual.

Not stored; calculated on demand.

Does not increase model size significantly.

6.

Import Mode

Data is stored inside Power BI.
Faster performance.
Supports full DAX features.

Direct Query

Data remains in the source database.
Queries the database in real time.
Some DAX limitations may apply.

7. The Applied Steps pane records every transformation performed on the data, such as filtering rows, changing data types, removing duplicates, and renaming columns. It allows users to review, modify, or delete any transformation step.

8. Cardinality defines how records in one table relate to records in another table.

Types:

- One-to-One
- One-to-Many
- Many-to-One
- Many-to-Many

9. Cross Filter Direction determines how filters propagate between related tables.

Types:

- Single: Filters flow in one direction (recommended for most models).
- Both: Filters flow in both directions (used only when necessary).

10. The ALL() function removes filters from a table or column, allowing calculations on the complete dataset regardless of applied filters.
